Abstract

When taking out a mortgage from a Dutch financial institution, the financial institution will usually provide a fraction of the property value. How much that fraction is depends on the Loan-to-Value ratio. When taking out a mortgage, it is expected that the person that is in need of a mortgage to provide a downpayment for the remaining value. This means that people that need a mortgage will have to save up before they can buy a house. As saving up could be an obstacle if the downpayment gets too big, crowdfunding the remaining value could be a solution.

Such crowdfunding platforms already exist. In fact, they are increasing in popularity. There are a variety of crowdfunding platforms for different needs, such as for entrepreneurs seeking investments for their projects. However, there is one thing all these platforms have in common and that is that there is always a central point of trust, resulting in unneeded costs for the users of the platform.

This thesis presents the development process of researching and implementing a decentral market where mortgages can be crowdfunded. We have created a system that does not have a central point of trust, but it does connect people that need funding with investors and financial institutions.

An earlier bachelor project has already implemented a decentral marketplace to trade digital currencies. At first, the idea was to re-use their implementation. However, after the research phase we came to the conclusion that their implementation was no use to our mortgage market, as their marketplace is specifically designed for trading digital currencies. Therefore we made our own. To ensure more trust into our market, we used a blockchain to save the agreements that are made between the users. The blockchain ensures that the agreements made cannot be changed. Therefore, when an agreement is added to the blockchain the agreement is final.

Our final product is a working decentral mortgage market, which enables people that need funding to place loan requests, receive mortgage offers and investment offers from financial institutions and investors. Financial institutions are able to receive loan requests and provide mortgages. Investors are able to search for investment opportunities, view campaigns that need funding and place investment bids on those campaigns. This is all possible without the risk of the mortgage market platform from getting shut down. The mortgage market can be run using a terminal or using the graphical user interface, making it accessible for all types of users.

Preface

This thesis describes the development process of researching and designing a decentral market for real-estate finance. This project has been initiated as part of the course TI3806 Bachelor Project in the Computer Science program at the Delft University of Technology. The project took place from early November 2016 until the end of January 2017.

There are several people we would like to thank for their support during the project. First we would like to thank our coach, dr. ir. Johan Pouwelse, for his valuable guidance and feedback. We would also like to thank our clients from ABN AMRO. Finally, we would like to thank Bart Gout and Leonard Franken (AFM) for supporting us with their knowledge about mortgages, and Martijn de Vos for answering questions and helping us overcome challenges we had during the development phase of the project.

Introduction

The mortgage market is a multibillion market that has seen some serious lows in the last couple of years. The high amount of borrowers defaulting their mortgage played a big role in the 2007-2008 financial crisis [42]. That financial crisis had a big influence on the world economy.

Taking a mortgage from Dutch financial institutions can be done as follows. First, the borrower needs to decide what the possibilities are, e.g. what are the total costs and how big can the loan be? When the financial situation of the borrower has been verified, a house can be chosen that fits the borrower's needs. When an agreement has been met with the seller of the house, a mortgage can be settled with a mortgage lender. Together with the provider it will be possible to choose for a mortgage type that fits the borrower's financial situation.

In the Netherlands, the current maximum mortgage limit is 102%. Each year it is being lowered with 1% till 2018, when the maximum mortgage limit will be 100% [19]. The CEO of the Dutch National Bank [12], Klaas Knot, wishes to see the maximum mortgage limit be reduced to 90% by 2028 [39]. While the maximum amount of the mortgage is a legal limit, financial institutions will usually only provide a fraction of the property value amount. How much the financial institutions will provide exactly depends on the Loan-to-Value ratio [24], which differs case to case. Instead it is expected that the borrower provides a downpayment of the remaining value. The large downpayment means that people that are looking to buy a house will have to save up before they can buy a house.

To enable buyers to get the capital they need but do not have, crowdfunding is a solution. Such crowdfunding platforms already exist and they are becoming more popular. Some give the opportunity to crowdfund mortgages while others are more general and provide a place for entrepreneurs to find investments for their projects. These projects range from opening a new shop to projects like installation of personal solar panels. What these platforms all have in common is that they are centralized, which means that there is a third party that connects the investors with the investees. The crowdfunding services they provide are not for free, which results in unneeded costs for the users of the platform. A way to eliminate the unneeded costs is to make a decentralized platform, where no middleman is needed.

2

Problem description

In this chapter we define the problem, give a description of the client, and analyze related initiatives. Further it contains the project requirements and the description of the screens we have designed.

2.1. Problem definition

It is currently very difficult for an average citizen to get a mortgage. Only borrowers with minimal risk of defaulting are given a mortgage. As the value of houses keep rising, it becomes increasingly difficult for people to receive a mortgage. Additionally, because of the mortgages not covering the total cost of the estate, the only possibility is to make a large down payment. For a lot of people, and especially for young adults that recently joined the working force, down payment is not an option. At the same time, interest on saving accounts is so low that it does not covers inflation. Investing could bring a solution to savings losing value over time.

There is a need for a system that connects these parties together. The parties consist of the **borrower**, the **investor** and the **financial institution**. These three stakeholders all have their own incentive to work with each other. The borrower needs a bank to settle a mortgage and investors to fund the initial down payment. In return the public investors and the bank can receive interest on their respective investments. To solve the mentioned problems, we focus on creating a platform where mortgages can be partially crowdfunded.

Crowdfunding platforms are getting increasingly popular to create funds for projects in which banks are not investing. Platforms on which it is possible to get your mortgage crowdfunded already exist, yet on all of these platforms there is a central party that connects the investors with the borrowers. The central party is not only unneeded, but also brings unnecessary costs and risks. Bringing down the middleman will also bring down the whole system.

To avoid that the whole system collapses when one of the key parties drops out, the system needs to be decentralized. During the project, we will strive to create a platform where people can find mortgages that are funded by both banks and investors. A person will be able to apply for a mortgage where the bank can fund a fraction of the loan (e.g. 70% of the total loan). When the mortgage has been accepted the loan request will be transferred to an open market place where investors can crowdfund the remaining part of the mortgage. The interest rate on these investments will be negotiated between the borrower and the investor.

The aim of this project is to create a decentralized market where it is possible to crowdfund a mortgage. The system will not be controlled by a single party, but mostly by supply and demand.

When we started the project, the problem description differed. The original project description can be found in appendix A.

2.2. Client description

The client for this project is ABN AMRO [1]. ABN AMRO is collaborating with the TU Delft Blockchain Lab [3], which is part of the Tribler team [47], on the development of blockchain [4] applications. They aim to create some complex blockchain applications that are suitable for use in practice, within half a year [25]. With the collaboration, ABN AMRO wants to improve their knowledge on blockchain technology, especially on the practical application of distributed digital ledgers.

TU Delft has been researching blockchain since 2007. The research at TU Delft focuses on developing next-generation blockchain technology that is trustworthy and scalable. Their scalable blockchain is based

on tamper-proof secure timelines and graph-based data structure. This project will be built on previous work that has been done at the Blockchain Lab [48]. All of their work is shared with the open source community.

2.3. Required technologies

Being a decentral application, there can be no central server. All communication must be shared between actors in the system, with no central point of trust of authority. This can be achieved by creating a peer-to-peer network for the decentral real-estate market application. Originally the assignment was to extend the existing decentral market[26] to include crowdfunded mortgages. This market community was built upon the Distributed Permission System (Dispersy) [11] for peer-to-peer networking. That means that building upon Dispersy is part of our assignment.

Furthermore, this being a project for ABN AMRO in collaboration with the TU Delft Blockchain Lab for development of blockchain applications, it is expected that the market utilize blockchain technology in some way.

2.3.1. Dispersy

Dispersy is a fully decentralized platform designed to simplify the creation of distributed communities. It uses elliptic curve cryptography [23] in their simple identity and messaging system to securely and anonymously identify different nodes. It can run on systems consisting of a large number of nodes, without having the need for any server infrastructure. Each node is equally important and they run the same algorithm to perform the same tasks, which increases the robustness of the system. Data is forwarded between nodes and will eventually reach all nodes.

2.3.2. Blockchain

A blockchain is a distributed database that holds a steadily growing list of data called *blocks*. Each block contains, among other things, a timestamp and a link to the previous block. Within the system, data is being exchanged and authentication between the nodes takes place. The data can not be manipulated or falsified, due to the distributed system. Using a blockchain it is not necessary that a third party ensures the reliability of a transaction.

2.4. Project requirements

To prioritize the requirements, we used the MoSCoW method [29]. The requirements are subject to change during the development phase.

2.4.1. Must Have

The Must Have provides the Minimum Usable SubseT (MUST) of requirements that the project guarantees to deliver. These are the core functionalities and without these, the product cannot be delivered. These requirements have the highest priority.

- Borrower can place loan requests.

- Borrower can upload documents needed to apply for a mortgage.

- Borrower can see offers they get from investors and financial institutions.

- Borrower can accept offers they get from investors and financial institutions.

- Investor can see which campaigns are available.

- Investor can place an offer on a campaign.

- Financial institution can create a quote for a mortgage.

- Financial institution can see their pending loan requests.

- Financial institution can review pending loan requests.

- Financial institution can accept pending loan requests.

- Python 2 to be able to interface with Tribler and Dispersy.

- PyQt for the GUI.

- Tests and coverage.

- Full transparency. Everything open-source.

2.4.2. Should Have
The Should Have requirements are important but not vital. The product is still viable without these functionalities. It has the highest priority after the Must Have requirements.

- Borrower can reject offers they get from investors and financial institutions.

- Investor can see which campaign they have currently invested in.

- Financial institution can see which mortgages they currently have provided.

- Financial institution can reject pending loan requests.

- Scalable.

- Blockchain technology.

2.4.3. Could Have
The Could Have requirements are wanted or desirable, but less important than the Should Have requirements.

- Borrower can see which campaigns are available.

- Investor can resell their investment.

- Investor can invest passively.

- Financial institution can see which campaigns are available.

- Financial institution can determine the maximum interest rate that a borrower is allowed to pay an investor for the loan.

- Financial institution can recommend an interest rate that the borrower can pay to an investor for the loan.

- Secure storage and transfer of information.

- Encrypt and decrypt user documents.

2.4.4. Won't Have
The Won't Have requirements will not be implemented in the final solution, because they are out of scope for this project.

- Borrower can see how much has already been paid off.

- Investor can see how much has already been paid off.

- Financial institution can see how much has already been paid off.

- Regulator can see the total financial health of all the active loans.

- Transactions can be done through the system.

- Smart contracts to ensure binding agreements between stakeholders.

- The system can do a risk assessment.

Smart contracts are out of scope for this project and will be researched and implemented by a PhD student after we have finished this project. Besides smart contracts, transactions through the system are out of scope for this project too. Because transactions can not be done through the system, borrowers, investors and financial institutions will not be able to see how much has already been paid off. Therefore the regulator can not see the total financial health of all the active loans. We have decided that the system will not be able to do a risk assessment, as this would be too complex and will not be achievable in the duration of this project.

2.5. Screens & Workflow

Based on the requirements, a list of pages the program should have to achieve these goals has been compiled. The screen can be either for borrowers (**B**), investors (**I**) or financial institutions (**F**).

Profile (BIF)

The profile screen differs depending on the role of the person that is logged in. It is used to save and update personal information. Investors only need to enter their name, email address and IBAN. Borrowers need to enter more personal information and they can upload personal documents such as payslips and proof of identity.

Portfolio (BIF)

The portfolio screen differs depending on the role of the person that is logged in. Borrowers can see, accept and reject the offers they got from banks and investors. Investors can see the loans they invested in, their pending investments, and they are able to resell their loans to other investors. When they are reselling a loan, they can accept en reject the offers for that loan. Financial institutions can see which mortgages they currently have.

Place Loan Request (B)

Borrowers can place a loan request, which will then be sent to all financial institutions of their choice. This will include information on the house, its price, and how much money they want to borrow. There will also be a box to write a small description, so an investor can learn more about who they are investing in.

Pending Loan Request (F)

Financial institutions can see all pending loan requests. They can review each of the requests and accept or reject them. When they accept a loan request, they have to enter the details about the mortgage here, such as interest and duration.

Open Market (BIF)

On the open market all investing opportunities are presented to all roles, but investment can only be made by investors. Key things to show are the rating of the mortgage, the duration of the loan, risk and type (new or aftermarket). Search and filter functions will be included as well.

Campaign Bids (BIF)

The Campaign Bids screen can be reached from the open market by selecting a campaign, and shows the current bids that investors have made in the campaign. Additionally, from here it is possible for investors to place a bid of their own by entering the amount they want to invest, the duration of the loan and desired interest rate.

2.6. Related initiatives

To get some more insight into the current crowdfunding market, it is necessary to analyze initiatives related to crowdfunding, crowdfunded mortgages and crowdfunded loans. We found a couple of these initiatives of which thirteen will be discussed in this section.

2.6.1. Jungo

Jungo [21] is a mortgage bank, with the ability to crowdfund your mortgage. All clients whom are accepted by the bank will guaranteed get a mortgage. But Jungo differs from normal mortgage banks by making it possible for 3rd parties and institutional investors to provide a part of the mortgage in return for an attractive interest.

At the moment of this writing it is not yet clear what the application process is for a mortgage via Jungo as they have not yet launched their service. All borrowers will undergo a risk assessment based on the 'Code of Conduct for Mortgage Loans' [7].

Investors can choose which project they want to finance, for an amount between €250 and €80.000. The provisional interest is between 3% and 3.5%. They pay the money via an iDEAL transfer to the person requesting funding, and will be paid back monthly for up to 8 years. The length of the investment varies per Jungo campaign.

However, only 20% of the mortgage sum can be crowdfunded. The remaining amount must be provided by Jungo itself. As this seemed as a constraint set by law we reached out to a Leonard Franken (supervisor InnovationHub) from The Dutch Authority for the Financial Markets (AFM) [45] to get some insight. According to him the limit to the amount that can be crowdfunded seems to be set by Jungo itself, as no limit has been set by law. He then mentions that this could have been done to make it more attractive to investors. From the investor's perspective 30 years is a long time to lend out your money and the shorter the duration, the harder it becomes for the borrower to pay back the debt. By making a smaller sum that needs to be paid back in a shorter period of time the deal becomes more attractive for both parties.

Investors are protected from borrowers who are not able to live up to their obligation by a fund controlled by Jungo to continue paying investors when a borrower misses a payment. This fund is limited however.

Thus Jungo can be seen as a mortgage bank that also functions as intermediary for individuals and institutional investors who wish to invest in a mortgage. Finally they also provide a guarantee (up to a certain point) that your investment will be returned.

2.6.2. Blandlord

Blandlord [2] is a platform for crowd ownership of homes. The idea behind the platform is that home owners can put their house for sale via Blandlord, even if the home is inhabited (the new landlord of the renters will become Blandlord). These houses can then be bought by a number of investors who can buy a percentage of the house. The rent income is then shared among investors depending on the percentage that they own. Thus Blandlord is not only a platform for selling the houses, it also functions as a letting agent.

All homes must be 100% owned by the owner before being placed on Blandlord. To minimize the risk that the homes stay empty due to lack of renters, only houses in areas with a healthy house market are accepted, as judged by Blandlord. Furthermore, an extensive audit of the condition of the house is required as a prerequisite of being able to list the house on Blandlord, to prevent the investors being faced by unforeseen costs.

Investors can buy shares in a house, with the minimum investment amount being €100. The value of the shares are directly correlated to the value of the house. They are paid their share of the rent on a monthly basis, based on the expected rental income. The costs of using the service is a 1% transaction fee on all transactions (buying/selling shares).

2.6.3. Greencrowd

The focus of Greencrowd [18] is to provide a crowdfunding platform for sustainable energy projects such as installation of solar panels, wind power, et cetera. These projects will in turn provide income by selling the power or service, or for instance lower the energy costs of a building that has installed solar panels.

Organisations can present a plan for a sustainable energy project, which will then be analyzed by Greencrowd to make sure the plan is realistic. They will also analyze the financial risks and assign a grade to each project, ranging from A to G. The interest an investor can expect is tied to the grade. The riskier the project, the higher the return. A project has a certain amount of time to get financed, if the finance goal is not reached before the deadline, all investors will be returned their money.

Investors can invest in all running projects, with the amount varying per project. The running time of the loan also varies per project. The only constant is that the interest is always tied to the grade the project received. Payments also vary per project, which can be monthly or quarterly, and they can include special provisions for paying off a loan earlier (the investor then receives a bonus from the investee).

2.6.4. Fundrise

Fundrise [14] is an online platform where individuals, accredited or non-accredited, are able to directly invest in commercial real estate projects from real estate companies, without the middleman. The main difference between the Fundrise eREITs (electronic Real Estate Investment Trust) and other REITs, is that Fundrise is

more transparent and has roughly 90% lower fees. Fundrise enables investors to choose in which eREIT they want to put capital in.

To submit a project for a loan, the companies need to indicate the amount to raise and the project type, and they have to upload relevant documents needed for the application. First the information will be screened to ensure investment is consistent with Fundrise standards. Then follows the in-depth analysis, which includes an on-site visit by a member of the Fundrise team. When the project is accepted, it will receive a Fundrise rating, a letter rating ranging from A to E so that investors can easily compare different investments.

The minimum investment is $1.000 and the maximum may not exceed 10% of the investor's gross annual income or net worth. The fund transfer is done via bank account. When investors get their return is specific to each listing. When available, a distribution schedule can be found in the offering documents for that investment. Generally investors can expect to receive distributions quarterly. Asset management fees are between 1% and 1.5%.

In the event that a company is not able to pay back the loan, the eREIT will bear the risk. The eREIT will pay the investors to the extent of any deficiency between the value of the collateral and the amount of the loan.

2.6.5. RealtyShares

RealtyShares [38] is a real estate crowdfunding platform that lets accredited investors choose what they invest in. Investors have the choice to invest in one specific property or in a group of properties. RealtyShares offers commercial and residential real estate projects.

To apply for financing, relevant information and documents should be provided by the borrower. RealtyShares then reviews whether the borrower prequalify based on their track record, financial strength and expertise. After the pre qualification, borrowers will be thoroughly reviewed based on their investment strategy, financials, legal standing, and property condition/location.

Investors can start investing from $5.000. The funds transfer is via bank account. Depending on the type of investment, investors get their return either quarterly or monthly. Investor fees have a maximum of 2% of the invested amount. RealtyShares offers investors to loan their money supported by a collateral, a specific real estate property or pool of properties.

2.6.6. Collin Crowdfund

Collin Crowdfund [8] offers linear loans through crowdfunding to established businesses and startups. Innovatively Collin returns to the basics of banking, where the investor decides what they invest in. Collin also cooperates with banks to demonstrate what is realistic and to give the business the opportunity they deserve. That combination ensures that the investor makes a good return at a reasonable risk and that the business can realize their ambitions.

To apply for a loan the business has to indicate the desired loan amount and the purpose for the loan, and they have to upload relevant attachments for their loan application. Collin then provides the business with a Crowdfund Coach to assist with filling out the Collin Credit Score model, which is a risk assessment that tests the company in terms of solvency, profitability and liquidity. The Collin Credit Score produces a D&B rating [10] and the boundaries of the interest rate the business is allowed to set. Collin either approves or rejects the loan application using all of that information.

Investors can choose which projects they want to finance. Private investors can invest for an amount between €500 and €80.000 and corporate investors can invest from €500 with no upper bound. They pay the investment via an iDEAL transfer to the business requesting funding and will be paid back monthly for the duration of the project, which can be anywhere between 6 months and 10 years.

To protect investors from businesses that are not able to live up to their obligation, Collin continues paying investors for one month. When the business is not able to pay the investors back after that month, there will be no payment of interest to investors.

Collin asks for a small fee from both the business and the investors, which makes it possible for Collin to take care of the payments for both sides. For every investment a management fee is calculated annually at a rate of 0.85%. The business is asked for a one-time fee of 1.9% for a successful loan and a monthly fee of 0.05%.

2.6.7. Upstart

Upstart [50] is a platform that allows people to obtain loans with a fixed rate. Upstart does not only look at credit scores, because they believe people are more than just credit scores. They use a model that considers

the school the borrower has attended, their field of study, their academic performance, and employment history in addition to their credit history. That allows Upstart to offer people the loans they have earned.

To apply for a loan at Upstart, borrowers have to fill in an online application which will include information about their academic credentials, work experience and what they plan on doing with the loan proceeds. Upstart also verifies the borrower's personal and credit information as part of the application process.

Investors cannot choose in which project they invest, because loans are not visible publicly on Upstart. Investors can invest for a minimum investment amount of $100. All loans are fixed-rate loans with a 36 or 60-month repayment period. Investors will get an investor account on Upstart, to which they can transfer money to invest or to transfer their returns to their own bank account.

Upstart determines the interest rate using the borrower's education, credentials, work experience, and credit history. This means that the interest rates are different for each loan. Once the interest is determined, all loans have a fixed-rate interest. The loans are unsecured obligations of the borrower and are not supported by any collateral.

As compensation for the marketing and ongoing servicing of loans, Upstart receives servicing fees that are paid from the origination fees that are collected from borrowers. Borrowers pay a one time origination fee that is between 1% and 6% of the target loan amount. Investors pay an annual servicing fee of 0.5%.

2.6.8. CrowdAboutNow

CrowdAboutNow [9] is a crowdfunding platform that makes it possible for entrepreneurs to start a crowdfunding campaign. They will support the entrepreneurs whenever they need it. CrowdAboutNow makes it possible to invest safely, both legally and technically.

To apply for a loan, entrepreneurs have to take a test to determine if their plans are suitable for crowdfunding. If their plan is suitable, an account manager will get in touch with the entrepreneur to discuss their plans.

Investors can choose the projects they want to invest in themselves. Investors can invest for an amount up to €80.000. They pay the investment via an iDEAL transfer, for which a fee between €0.70 and €0.80 is asked. It is not clear in what period of time and at what interest rate the investors will get their investments back.

To minimize the risk for investors CrowdAboutNow verifies if the entrepreneur is willing to use its own network to invest its venture capital. CrowdAboutNow verifies the identity of the entrepreneur, the registration of the company, and its bank account. They also meet with the entrepreneur in person. If the entrepreneur has been registered for less than 3 years at the Chamber of Commerce [6], a partner that understands the industry will act as the nominating party. Should there not be enough investors to reach the loan target, all investors will get their money back.

CrowdAboutNow advertise entrepreneurs' crowdfunding campaigns, they give legal advice, and take care of the financial transactions. They do this for a one-time entry fee of 1% of the loan target and a 2% annual fee when the campaign is successfully funded.

2.6.9. Kapitaal op Maat

Kapitaal op Maat (KoM) [22] is a platform that makes it possible for different projects to get crowdfunded. Possible project funding sum can range from €25.000 to €500.000. Individual users can invest any amount between €100 and €50.000. Corporate investors do not have a hard ceiling, but both types of investors cannot invest beyond the amount that is needed to get the project fully funded.

To apply for a loan the company or entrepreneur needs to present the website with a business plan of the venture. After that a fee of €395 is paid to KoM to examine the presented offer and determine the risk of the venture. Additionally, if the venture is accepted, another fee of €350 must be paid to publish the venture on the website. The borrower will receive guidance with the right presentation of the offer. The calculated risk of the venture, which consists of a grade from A+ to C-, determines the interest. This will range from 5.5% for the lowest risk ventures (A+) and 9.5% for the highest risk ventures (C-).

When an investment is made, an initial fee of 0.9% of the investment is paid. All the investments are sent to the escrow account of KoM and stored until the the funding goal is reached. If this goal is reached, a fee of 4% must be paid by the borrower to receive the funding. When the fees are paid and the transactions are made, the borrower will continue to pay the escrow a fixed rate every month until the investment and interest are completely paid off. After that, the escrow distributes the amount accordingly among the investors.

2.6.10. Geldvoorelkaar

Geldvoorelkaar [15] is a crowdfunding platform where Dutch corporations and individuals can invest in national, small to middle sized ventures.

The platform provides different types of loans which consist of: Fixed-rate, Interest-only and Convertible debt loans. The duration of the loan can range from 6 to 120 months. This can be as little as €1.000. There is no limit to how much an entrepreneur can ask, but no funding will be received until the loan goal is reached.

The fees for a funding request are €125 for private investors and between €350 and €500 for corporate investors. Additionally, when the loan goal is reached, the borrower pays a small fraction of the loan goal as success fee each year for the duration of the loan. This fee can range from 0.5% to 7.9% of the loan goal.

Geldvoorelkaar does background checks on everyone asking for a loan. Before a request can be made, the borrower has to present a business plan and a financial report. This is used to determine risk of the venture, which in turn will be used to determine interest of the loan. The higher the risk, the higher the interest. This is usually somewhere between 4% and 10% interest. After the transactions are made, the investors receive monthly payments by the borrower until the loan and interest are completely paid off.

2.6.11. Bouwsteen

Bouwsteen [5] is a new initiative that is going to be available in Q1 of 2017. They want to provide a solution targeted at groups that are not served adequately in the market yet, namely starters (employees and self-employed) and seniors. Their goal is to create a financing product for the private housing market that allows for a reduction in the monthly payments, providing flexibility to the homeowner. Since Bouwsteen have not launched their service yet, it is not clear in what way the mortgages they will offer will work and how they are planning on reducing the monthly payments.

2.6.12. Gradefix

Gradefix [17] is a new initiative by ABN AMRO to automate credit checks. It is completely different than the previous initiatives described in this section as it has nothing to do with crowdfunding, but credit checks are an integral part of any mortgage application. Gradefix calculates this score on the basis of the requester's bank transactions. By calculating the incoming and outgoing sums, and how much money is left at the end of each month, a credit rating is generated.

2.6.13. MoneYou

MoneYou [28] is a bank that gives borrowers a lot of freedom with their mortgage. Unlike other banks, MoneYou does not give any advice in any form. It is up to the applier to decide what is best for them and their situation. The applier decides the specifics of the mortgages such as mortgage type, loan duration and loan amount.

What makes MoneYou special compared to other banks is that they facilitate the mortgage and all of the steps to get a mortgage online. In other words, it is possible for people to apply for a mortgage and go through most of the steps online. Before an application can be made the applier needs to do a quiz on the MoneYou website. The quiz consists of multiple choice questions that should show that the applier knows what they are doing and has the financial knowledge and assets to take out the mortgage. The quiz and other submitted documents such as payslips and other financial documents are used by MoneYou to make a final verdict on giving out the mortgage or not. After the mortgage has been set, the definitive purchasing of the real-estate can be made with the help of a notary.

2.7. Development process

During the project we used the Scrum framework [40]. We worked in sprints of 2 weeks, and we focused on finishing a new functionality every sprint. Each chapter of this thesis reflects one sprint.

We held daily meetings within our group, we held meetings with our coach every week to discuss our process and progress, and we had a couple of meetings with our client to discuss our progress. The meetings made sure that we were able to stick to the goals of the client and to incorporate feedback that they provided. We developed the software using GitHub [16] for revision control. During the the development of our software we made use of Travis CI [46] and Jenkins [20] for continuous integration. Our project code can be found at `https://github.com/Jumba/mockchain-market`.

We were also required to send our code two times during the course of the project to the Software Improvement Group (SIG) [41]. We received a score and some feedback from them, and processed their feed-

back. How we addressed the feedback can be found in section 5.3. Their full feedback can be found in appendix G.

3

The customer journey

After centering our first two-week sprint around the orientation of the problem, we started working towards a demo for our client. We have also designed the system, defined an API and started working on creating the core functionalities in the graphical user interface (GUI).

The problem has three equally important stakeholders, as the system can not be functional with any of these stakeholders not present. These stakeholders are the borrowers, investors and financial institutions. In the following sections, the journey of each of the stakeholders will be discussed.

3.1. Researching the customer journey

Throughout the first sprint of the project, we concentrated on understanding the problem and related initiatives. Through analyzing the different initiatives, we came to understand more about crowdfunding real-estate.

Because our problem concerns people who need a mortgage, we had to understand how mortgages work too. The two most common mortgages are Linear and Fixed-Rate [30], which are available for starters. Bart Gout, our real-estate/mortgage expert, provided us a document that listed the required documents needed for applying a mortgage and a scheme showing the process of getting a mortgage. These documents can be found in appendix C.

From the related initiatives, which were described in section 2.6, we found out that there are existing crowdfunding platforms for real-estate. There is even a bank that facilitates the mortgage and regulates all the steps to get a mortgage entirely online [28]. A MoneYou representative explained that the required identity check can be delayed until the end when the borrower meets with the notary. Only the definitive purchase will have to be made with a notary. Thus the marketplace does not need to supply a way to verify the identity of a borrower.

3.2. Defining the customer journey

With the required information for the application process of a mortgage in mind, and thinking about what the financial institutions need in order to offer a mortgage, and considering what the possible options are for potential investors, we started defining the customer journeys. A flowchart of the journeys of all customers can be found in appendix D.

3.2.1. The borrower's journey

The borrower's journey starts when the person opens the market software. At this stage are two cases, either the person has used the software before or they have not. When they have used the software before, they can supply their private key to identify themselves. When they have not used the software before, a key pair has to be generated for the user. After receiving their key, this person is not yet a borrower, as this is a general step for both borrowers and investors.

After logging in they will be forwarded to their profile. On this profile page they can add or append all required personal information. The first time they fill in the profile they choose their role, which can be either borrower or investor. In this section the chosen role will be 'borrower'. Once the required fields are filled in

and all the needed documents are uploaded, a prospective borrower can go on to apply for a mortgage. If they have already applied for a mortgage, they can check to see if any offers have been received from banks or investors in their portfolio.

Applying for a mortgage is a fairly straightforward process as all required documents will have been uploaded to the profile. The user will have to supply mortgage-specific information, such as house information, the real estate broker, et cetera. They can also choose which banks to send the request to. Once sent, the only course of action is to wait for offers from the banks.

Once a mortgage offer is received, it will be shown to the borrower in their portfolio. The borrower can then elect to accept the offer, or reject the offer. Once a mortgage offer is accepted the crowd funding campaign will start. At this point the mortgage offer is placed on the open market where investors can submit investment bids. As with the mortgage offer from banks, offers from investors will be shown in the portfolio.

From now on the market software will take care of all the work until the campaign is either funded, or the time limit has passed.

3.2.2. The investor's journey

The investor's journey starts, like the borrower's journey, when the person opens the market software. They too, have to identify themselves using their private key if they have used the software before, or generate a new key pair if they are new users.

Once they have identified themselves, they are forwarded to their profile. There they can edit their personal information, such as contact information and IBAN. If it is their first time filling in the profile, they have to choose their role, which is either borrower or investor. In this section the chosen role will be 'investor'. After the required information is filled in, they are able to see their portfolio, search for investment opportunities, or choose to invest passively.

The portfolio page lists all of the investor's current investments, pending loan offers, and bids on their investment that they want to resell. They can monitor their investments, accept or reject investment opportunities and bids, and choose to resell investments.

If the investor chooses to actively search for investment opportunities, they can do so at the open market. When an investment opportunity has been selected, they can see the current investment bids on that particular opportunity and place a bid of their own. Their investment bids and the status of the bids will be shown in their portfolio.

The investor can also choose to invest passively. All they have to do is fill in the amount they want to invest, the approximate interest rate they want to receive for it, and the duration of the investment. When the loan offer is placed, the market software will automatically search for investment opportunities that matches the loan offer. The moment an investment opportunity has been found and is accepted by the borrower, it will be shown in their portfolio.

Ongoing investment opportunities can be placed on the open market, if the investor wants to resell their investment. They have to fill in the amount and the interest rate they want for it. Once other investors have placed their bids, the bids will be shown in the investor's portfolio for them to accept or reject.

3.2.3. The financial institution's journey

The financial institution's journey starts, like the borrower's and the investor's journey, when they open the market software. The financial institution has to identify themselves by supplying their private key. Unlike the borrowers' and investors' keys, their public key is already saved in the software to ensure that people can not pretend that they are a financial institution.

Once the financial institution has identified themselves, they will be able to see their portfolio. In their portfolio they can see the information on all of the mortgages that they currently have running.

From their portfolio they will be able to go to another page, on which their pending loan requests are displayed. On this page there is a list of all the loan requests from people who want to take a mortgage have submitted.

The financial institution is also able to view every one of those loan requests individually. On the individual loan requests page they will be able to view personal information about the borrower, including the documents that are needed to apply for a mortgage, and mortgage specific information, such as the house the borrower wants to buy and the amount of money they want to borrow. On this page they have the option to accept or reject the application. When they want to accept an application, they will have to fill in some details on the mortgage they want to give out. Once the application has been accepted, it will be sent to the borrower who can then decide if they want to accept or reject their offer.
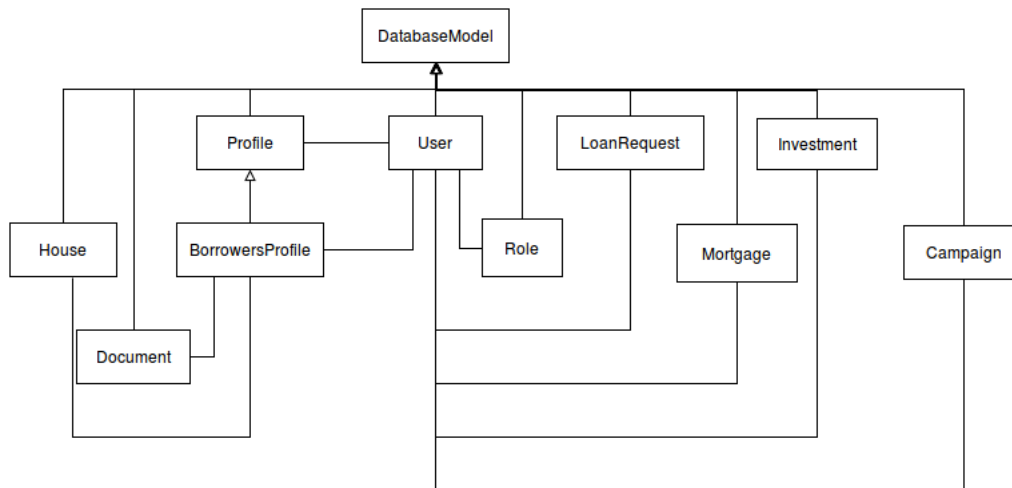

Figure 3.1: UML class diagram

Financial institutions also have the option to explore the open market. They will be able to see all current running campaigns and the bids that investors have placed on them, but they will not be able to place bids themselves.

3.3. Object-oriented analysis and design

In this section the object-oriented analysis will be documented. This analysis will use the problem description, as described in chapter 2, and the customer journey as the source to determine which objects will need to be represented in the system, how they will behave, and how they will interact with each other.

The first object identified is the **User**. This 'User' can be either a 'borrower', 'investor' or 'financial institution' which are immediately defined as **Role**s within the system. To simplify the system a user can only have one role. Depending on the 'role', certain information will be required from a user. For instance, it is required to know the current address of a borrower, since the financial institution needs to know where to send mail. But this information is not needed for the investor. Based on this, a **Profile** object has been created which includes all personal information of a user. To accommodate the extra information required for a borrower a **BorrowersProfile** has been created, which extends the 'Profile'. For a mortgage request, an array of documents is required. These will be stored in a **Document** object.

When a borrower wants to request a mortgage, a **House** object is created with details of the house and its price, which will be sent to the financial institution along with a **LoanRequest**. In this 'LoanRequest' the borrower can specify which type of mortgage, amount wanted, et cetera. As soon as a financial institution accepts the offer, this request is turned into a **Mortgage** which can be placed on the open market as part of a **Campaign** to crowdfund the remaining part of the mortgage. Finally, investors can start investing in mortgages by submitting **Investment** offers.

Since all objects will have to be encoded to be sent over the network, a **DatabaseModel** has been created from which all the other objects descent. This 'DatabaseModel' implements functions to encode and decode the objects and generating unique IDs. The relations between these objects can be seen in the UML class diagram in figure 3.1.

3.4. Defining the API

To ensure that 3rd-party programs can seamlessly access the decentralized mortgage market an API has been designed. We call this API the **Market API**. The goal of this API is to provide all functions required to be able to complete the customer journeys.

Based on the customer journey analysis, the following API functions have been created:

- create_user()
- create_profile(user, payload)

- create_loan_request(user, payload)
- create_campaign(user, payload)

- place_loan_offer(user, payload)

- login_user(private_key)

- load_profile(user)

- load_investments(user)

- load_open_market()

- load_borrowers_loans(user)

- load_borrowers_offers(user)

- load_all_loan_requests(user)

- load_single_loan_request(payload)

- load_bids(payload)

- load_mortgages(user)

- accept_mortgage_offer(user, payload)

- accept_investment_offer(user, payload)

- accept_loan_request(user, payload)

- reject_mortgage_offer(user, payload)

- reject_investment_offer(user, payload)

- reject_loan_request(user, payload)

- get_role(user)

The full API documentation has been included in appendix E.

3.5. Database structure

The market application stores all models in a key-value database. In this section this database will be defined, and implementation and design considerations will be rationalized.

During the planning phase of the market application, it was made clear that there would be a meeting with the innovation department of ABN AMRO on December 5th, 2016. We planned on showing them a basic clickable demo with the core functionalities, that we described in section 3.6. With this date in mind, a simple database layer was constructed to feed the GUI with the necessary data.

Due to the rapid pace of development, the decision was made to make it a key-value database, using the unique keys generated by the DatabaseModels as defined in section 3.3 along with the type of object as the keys. Thus the key of a *User* object is the user id and the type name 'user'. While a relational database would have been preferable due to the ability to search on all fields and the relations between tables, it was deemed too time consuming to implement and keep up to date while working towards the demo. Furthermore the current implementation of the market application has no need for these search abilities. However, future versions of the Market API could certainly benefit from advanced search functions, especially for the banks to be able to construct SQL queries for their administrative needs.

As seen in figure 3.2 the database consists of two layers. The upper layer **Database** implements the database API, which the Market API uses to communicate with the database. This database API then stores the data in the given *Backend* which can either be the **MemoryBackend** or the **PersistentBackend**. As the name suggests, the memory backend stores all data in RAM and is flushed as soon as the application is closed. The persistent backend uses SQLite for persistence. The Dispersy library implements a generic SQLite database in `dispersy.database.Database` which is used to implement the PersistentBackend. The purpose of the MemoryBackend is primarily for development and testing the code, whereas in production the persistent backend will always be used.

Figure 3.2: Database diagram

3.6. Visualising the core functionalities

Defining the journeys of the customers gives a good understanding of the functionality that user interface has to provide. The program's core functionality can be summarized by the following actions:

Placing a loan request

This can be done by a borrower when they want to apply for a mortgage. This action takes place in the **Place Loan Request** screen.

Reviewing loan requests

This can be done by financial institutions to assess a borrower's financial situation using their personal information and to determine if they are eligible for a mortgage. This action takes place in the **Pending Loan Request** screen, which consists of two different sections. The first section shows a list of all pending loan requests, and the second section shows a specific loan request. In the second section the financial institution can also accept of reject a loan request.

Accepting or rejecting a mortgage

This can be done by a borrower when they want to accept or reject a mortgage. This action takes place in the **Portfolio** screen.

Viewing campaigns

This can be done by all customers when they want to view the running crowdfunding campaigns. This action takes place in the **Open Market** and **Campaign Bids** screen, where they can view a list of all running campaigns and all bids on a specific campaign respectively.

Placing bids on campaigns

This can be done by investors when they want to make an investment on a campaign. This action takes place in the **Campaign Bids** screen.

Accepting or rejecting bids on campaigns

This can be done by borrowers when they want to accept or reject a bid that was placed on their campaign. This action takes place in the **Portfolio** screen.

A description of all of the screens that are mentioned above can be found in section 2.5. From these core functionalities, the first version of the GUI was made. We created the screens using Qt Designer [36], which is a Qt [35] tool for designing and building GUIs. To control what information is shown in the screens we used PyQt5 [34].

The screens that will be made in the next sprint exist to create a smooth user experience and to make the core functionalities more accessible. The core screens, along with all other screens, can be found in appendix F.

4

Let's get connected

In the previous sprint we validated and completed our data models, and started working on visualising the core functionalities. In this sprint we focused on visualising the rest of the screens, integrating Dispersy and the blockchain into the market, and implementing document transferring. We extended this sprint by one week, due to us wanting to implement multiple functionalities. We also submitted our code to SIG for a code quality check.

4.1. Visualising the market

In the core screens, that we described in section 3.6, not all functionalities of the market had been created yet. Those missing functionalities can be summarized by the following actions:

Entering personal information

This can be done by borrowers and investors to make sure that the parties involved know where the funding or interest needs to go. This action takes place in the **Profile** screen. The personal information will be shown in the **Portfolio** screen once an offer has been accepted.

Uploading documents needed to apply for a mortgage

This can be done by borrowers before they can place a loan request. This action takes place in the **Profile** screen.

Viewing current loans

This can be done by borrowers and investors when they want to see their accepted loans. This action takes place in the **Portfolio** screen.

Viewing current mortgages

This can be done by financial institutions when they want to see their accepted mortgages. This action takes place in the **Portfolio** screen.

Navigate between different screens

This can be done by all users when they want to view a different screen. This action takes place in all screens. All screens contain a navigation bar at the top of the page that contains all screens that the user has access to.

A description of all of the screens that are mentioned above can be found in section 2.5. With these functionalities the full version of the GUI was completed. All of the screens, including the core screens, can be found in appendix F.

4.2. System architecture and information flow

There are three big stages to the software, which are sending, accepting or rejecting a loan request, sending, accepting or rejecting a mortgage offer, and sending, accepting or rejecting an investment offer. For each of those stages we have defined the information flow in the system. The stages each apply to a model, which are the **LoanRequest**, **Mortgage**, and the **Investment** models respectively. The model specification can be found in section 3.3.

4.2.1. Loan Request flows

When a borrower sends a loan request to a financial institution, the financial institution can respond by either rejecting the loan request or offering a mortgage to the borrower. The loan request flows can be found in the sequence diagram in figure 4.1.

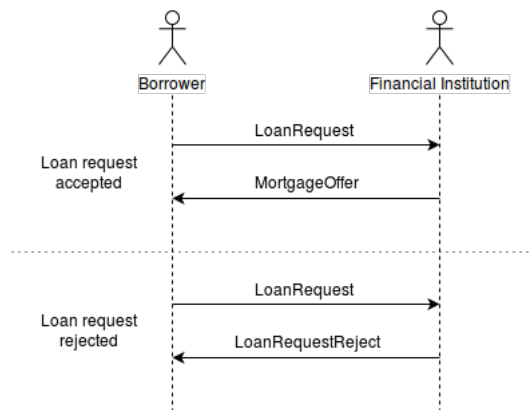

Figure 4.1: Loan request sequence diagram

4.2.2. Mortgage flows

When a financial institution has sent a mortgage offer to a borrower, the borrower has the option to respond by either rejecting or accepting the mortgage. When the borrower accepts the mortgage, the borrower also has to broadcast a message to other users to let them know that a new campaign has started. The mortgage flows can be found in the sequence diagram in figure 4.2.

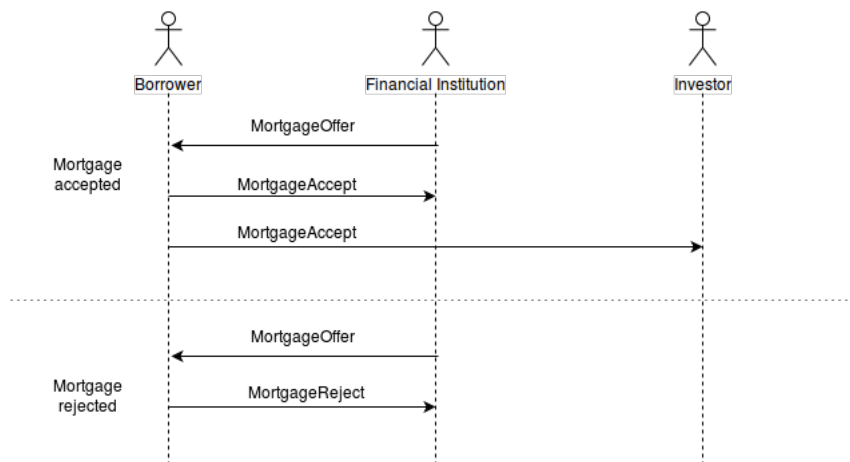

Figure 4.2: Mortgage sequence diagram

4.2.3. Investment flows

Once a borrower has accepted a mortgage, investors can place bids on their campaign by placing an investment offer on the borrower's campaign. The borrower can respond by either rejecting or accepting the investment. The investment flows can be found in the sequence diagram in figure 4.3.
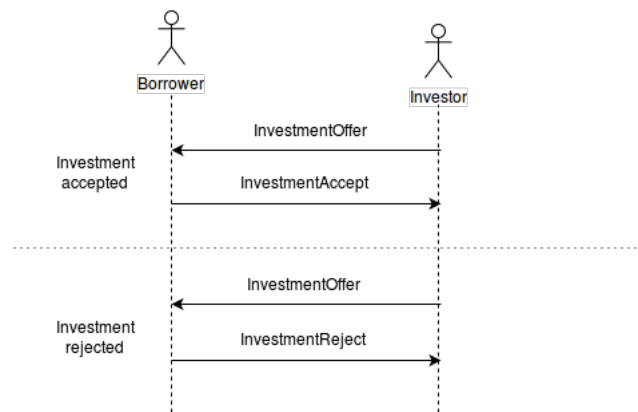

Figure 4.3: Investment sequence diagram

4.3. Integrating Dispersy

Dispersy lies at the heart of the decentralized mortgage marketplace. Integrating Dispersy to the market community proved to be a considerable challenge. It introduces a major paradigm change, since the program must work properly across different computers with each a different state. At the heart of Dispersy lies a simple identity and messaging system. These two systems have been fully integrated into the marketplace. In the following two subsections these integrations will be discussed.

4.3.1. Dispersy and Market Identity

Dispersy implements an identity system based on public/private keys. A 'Member' is someone who is part of a Dispersy community, and is identified by an unique public key. As soon as the member is connected, a 'Candidate' is created. A 'Candidate' is the object representation of the network address of the 'Member'. The member answers the question 'who', and the candidate the question 'where'.

Having read the Dispersy documentation prior to designing the API, the decision was made to identify the users in the market using public/private pair as well. To ensure that the identity of a user is always known offline as well as online, a key is generated and used for the creation of the Dispersy member and the market user. This key pair is then saved in the local database to be retrieved for future use. This process is completely transparent to the user.

The candidate however is not saved to any persistent database, rather to a memory location in the Market API. Candidates are volatile, IP address change often, connections get dropped, etc. Thus as soon as a user goes offline, the candidates list (which associates API 'User' objects with candidates) is lost and has to be rebuilt at the next connection to the community.

4.3.2. Dispersy message sharing

Dispersy implements a variety of ways messages can be sent between peers. The method of sending a message is called a 'Distribution' in Dispersy, and the recipient of a message is determined by the 'Destination'. There are multiple implemented distributions and destinations, but for this project only two destinations and distributions will be used.

The 'CommunityDestination' specifies that a message must be sent to a (specified) maximum number of (randomly selected) online members of the Dispersy community. To send a message to specific peers the 'CandidateDestination' must be used, which expects a list of peers to whom the message must be sent.

These destinations can be reached using two distribution methods. Using the 'DirectDistribution' the message is sent directly to a peer, then discarded. This distribution is used in the market application alongside 'CandidateDestination' to handle direct messages to peers. As mention above, the 'CommunityDestination' sends the message to a list of randomly selected peers, as such to ensure that all peers receive the message, 'DirectDistribution' is not advisable in this case, as after the randomly selected peers receive the message it is discarded. This is solved using the 'FullSyncDistribution'.

The 'FullSyncDistribution' instructs Dispersy to store the message for further propagation in the future. Furthermore, newly connected peers can ask online peers to send them all messages that they missed since they were last online. This message type is used for certain messages which ought to be shared to as many

peers as possible such as open campaigns, investments, etc. This distribution method will be used alongside the 'CommunityDestination' to share all public data.

When using 'FullSyncDistribution' models are constantly sent around in the network. Thus is it possible that two versions of the same model are in circulation. Take for instance the Campaign object, which is updated every time an investment is accepted to set the remaining amount that needs to be crowdfunded. To ensure that newer models aren't overwritten by older versions the notion of *signing a model* is introduced. By signing a model a user signs the hash of the content of the model, and sets the signing time. Thus by comparing this time it can easily be determined if a model is newer. This signing step takes place on all models before they are sent over the network.

4.4. Communication protocol specification

Defined in this section are the Dispersy messages and payloads, the communication between the Market API and the Dispersy Community, and the implementation of signed Dispersy messages.

In this section we will refer to two types of messages, 'Dispersy messages' and 'Market API messages'. These are not interchangable. Dispersy messages refer to implementations of Dispersy messages as defined in `dispersy.message.Message`. Market API messages on the contrary are defined by the market application to specify which handler should process the content of specific incoming Dispersy message. This was done in an attempt to limit the amount of Dispersy messages needed and prevent duplicate code.

First the Dispersy messages will be defined, followed by the Market API messages and finally the signed messages.

4.4.1. Dispersy Messages

As described in 4.3, messages lie at the heart of Dispersy. Six messages have been defined for the mortgage market community. In Dispersy a message must always have a 'Payload', which is a class which specifies which data will be carried in the message. These payloads must also have a decoder and encoder to serialize the data for transfer over UDP. To prevent having a host of payloads, encoders and decoders effort was made to make the payloads as general as possible to enable re-use. The payloads implemented are:

DatabaseModelPayload
> A payload with two attributes: 'fields' and 'models'. Where fields is the list of keys pertaining to Database-Models in 'models'.

APIMessagePayload
> This payload is similar to the DatabaseModelPayload, but with an extra attribute 'request'. This request field is used to specify which API message handler needs to be used.

SignedConfirmPayload
> This payload holds the following fields: 'benefactor', 'beneficiary', 'agreement_benefactor_encoded', 'agreement_beneficiary_encoded', 'sequence_number_benefactor', 'sequence_number_beneficiary', 'previous_hash_benefactor', 'previous_hash_beneficiary', 'signature_benefactor', 'signature_beneficiary', 'time'. These hold the keys of the two signing parties, the agreements of both parties (which should be equal), the sequence number of the block in the blockchain (defined in section 4.6), the hash of the previous item in the blockchain, and the signature of the message. Finally the time is saved.

The messages using these payloads are now defined.

introduce_user
> Sent as a reply to the built-in Dispersy message to introduce oneself to other nodes (`Community.on_introduction_response`). Contains a 'DatabaseModelPayload' with the user object.

api_message_community
> This is an API message sent to the entire community using the FullSyncDistribution type. FullSyncDistribution enables the gossiping of messages, which will ensure that users who log in in at a later time can get the message with a 'dispersy-sync' request. Example usage is for instance propagation of a new campaign. These messages are saved in the Dispersy database for further propagation.

api_message_candidate

This is an API message sent directly to one or more explicitly given candidates. All communication between a borrower and a bank happens through direct messages. These messages are discarded directly after being received.

signed_confirm

The signed_confirm message is specifically created to seal an agreement between two parties. Using the 'DoubleMemberAuthentication' provided by Dispersy, it requires that both parties sign the message if they agree with the message content. The message content being either a 'Mortgage' or 'Investment'. Thus before signing the message the system checks if the offer received is consistent with what has been agreed with. Only agreements which have passed through the signed_confirm process are treated as final and binding. More information about how signed_confirm is implemented can be found in section 4.6.2.

4.4.2. Market API Messages

In this section we describe the messages that are needed for the Market API (see 3.4) and its communication protocols which were described in section 4.2. These messages are different from the Dispersy messages described in section 4.4.1. The Market API messages will be shared across the network in the same Dispersy payload. This was done to remove the amount of duplicated code since all API messages have the same payload format.

LoanRequest

A LoanRequest message is sent by a borrower to a financial institution, when they create a loan request. The payload of the message contains the objects LoanRequest, House and Profile.

LoanRequestReject

A LoanRequestRejected message is sent by a financial institution to a borrower, when it rejects a loan request. The payload of the message contains the LoanRequest object.

MortgageOffer

A MortgageOffer message is sent by a financial institution to a borrower, when it accepts a loan request. The payload of the message contains the LoanRequest and Mortgage objects.

MortgageAcceptSigned

A MortgageAcceptSigned message is sent directly by a borrower to a financial institution, when they accept the mortgage offer. The payload of the message contains the Mortgage and Campaign objects.

MortgageAcceptUnsigned

A MortgageAcceptUnsigned message is sent by a borrower to all other users when they accept a mortgage offer. The payload of the message contains the LoanRequest, Mortgage, House and Campaign objects.

MortgageReject

A MortgageReject message is sent by a borrower to a financial institution, when they reject a mortgage offer. The payload of the message contains the Mortgage object.

InvestmentOffer

An InvestmentOffer message is sent by an investor to a borrower, when they place an investment offer. The payload of the message contains the Investment and the Profile object.

InvestmentAccept

An InvestmentAccept message is sent by a borrower to an investor, when they accept the investment offer. The payload of the message contains the Investment and the BorrowersProfile object.

InvestmentReject

An InvestmentReject message is sent by a borrower to an investor, when they reject the investment offer. The payload of the message contains the Investment object.

CampaignBid

> A CampaignBid message is sent by either an investor or a borrower, when they place a bid on a campaign or accept or reject a bid respectively. The payload of the message contains the Investment and the Campaign object.

4.5. Document Sharing

Dispersy is a great platform to host the distibuted market. The program uses the Dispersy message packages to transfer different payloads between users. While that works very well for small payloads, its maximum payload size can be too small to hold a document. While theorically it is still possible to send larger documents over dispersy it seemed more practical to use a protocol like TFTP [43] to transfer the documents.

To transfer the documents the program uses a module named *tftpy* [44]. With this module files can easily be uploaded to a server or downloaded from a server. In this case we want to upload the documents of a borrower to the banks that were chosen during the placement of a loan request.

For simplicity, we make the assumption that the banks are always online and are hosting a TFTP-server and we also make the assumption that every user needs to upload the same set of documents. Furthermore, we assume that when the transfer of the documents fails we will be able to try to transfer them again at a later date.

When the user places a loan request, all files are added to a queue and uploaded to all chosen banks one by one. If something goes wrong with transferring the documents, the jobs are saved to be re-sent on a later date.

4.6. Blockchain

To ensure that no one can lie about an agreement they have made, a blockchain is used. We re-used the MultiChain [31], but changed the body to save specific information relevant to our market. Another change is that we use limited sharing in our blockchain. Every block in the blockchain stands for an agreement between two users of the market. Only these two users have this block in their blockchain. The blockchains of these two users will not be synced with each other to form a larger blockchain for both users.

4.6.1. Architecture

The blockchain consists of individual blocks. Every block contains the fields in the SignedConfirmPayload listed in 4.4.1 and two other fields: 'previous_hash' and 'sequence_number'. The contents of a block can be seen in figure 4.4. The agreement data, as shown in the figure, is the same for both users that have the block in their blockchain and this is the part that gets hashed. The last two fields are different for every user. The 'previous_hash' is the hash of the latest block in the blockchain and the 'sequence_number' is the number of the block to be added, which should be the previous sequence number plus one.

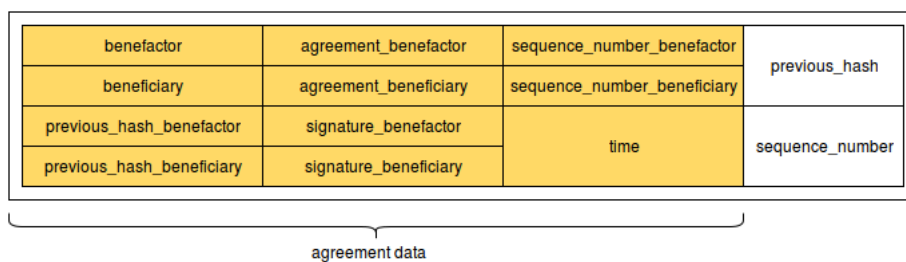

Figure 4.4: The fields in a block

The blocks of a blockchain are linked to each other through the hashes of the blocks. As each block contains the hash of the block before them, an ordered chain of the blocks is created. Another way to order the blocks to get the whole chain is by the block's sequence number. By using the sequence number of a block, we do not need to traverse through the hashes to get the chain. A graphical representation of a part of a blockchain can be found in figure 4.5. In this figure it can be seen how the blocks are linked to each other.
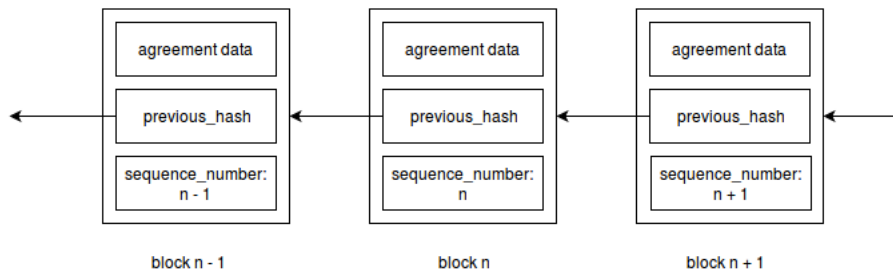

Figure 4.5: A chain of blocks in a blockchain

4.6.2. Signed messages and the blockchain

Dispersy implements signed message, which are messages which are signed by two or more parties. Each party signs the payload using their private key. The purpose of these messages is to prove that the parties all agree over the content of a message.

When the beneficiary (borrower) accepts a mortgage offer or an investment offer, the benefactor (bank or investor) will create and send out a Dispersy signature request message, with only the request part filled in, to the beneficiary. This message contains the SignedConfirmPayload listed in 4.4.1, but not all fields are filled in by the benefactor. The fields 'beneficiary', 'agreement_beneficiary', 'sequence_number_beneficiary', 'previous_hash_beneficiary' and 'signature_beneficiary' will be filled in by the beneficiary. We call this the response part. The benefactor persists the message and the corresponding block. A hash will be created from the message.

Upon receiving the signature request message, the beneficiary decides whether to accept or drop the message. This decision is made by comparing the agreement sent by the benefactor with the agreement the beneficiary has in its local database. When it has been decided to accept the message, the beneficiary will create and sign the response part of the message, and send it back to the benefactor. The message that is being sent back is called the signature response message. The beneficiary persists the message and the corresponding block. A hash will be created from the message.

Once the benefactor receives the signature response message, a final check will be performed. If the 'agreement_benefactor' and 'agreement_beneficiary' are the same, and there are no inconsistencies in the payload, then the benefactor will accept the message. At this point the signing process is complete. The benefactor updates the message and the corresponding block. A new hash will be created from the message.

A sequence diagram of the signed messages protocol can be found in figure 4.6

Figure 4.6: Signed messages protocol

4.6.3. Storage model

The blockchain is stored in a SQLite database. The same database used for the market application (see 3.5) is utilized for this purpose, with a table specifically for the blockchain. An interface **BlockChain** has been defined in `market.database.backends.BlockChain`, which must be implemented by all backends supporting the blockchain. Currently only the **PersistentBackend** supports the blockchain.

The BlockChain interface defines the following public functions:

add_block

Persist a block to the blockchain. This can be an incomplete block, which is only completed once it is updated with the information from the beneficiary.

update_block_with_beneficiary

Update an existing block with information from the beneficiary. Only the relevant fields are updated with the new data.

get_latest_hash

Get the hash of the latest block in the chain.

get_latest_sequence_number

Get the sequence number of the latest block in the chain.

get_next_sequence_number

Get the sequence number of the latest block in the chain plus one. If there is no latest block, the next sequence number is zero.

get_by_hash

Returns a block saved in the chain with the matching hash.

get_by_public_key_and_sequence_number

Returns a block saved in the chain where the given public key is equal to either 'benefactor' or 'beneficiary', and the given sequence number is equal to 'sequence_number_benefactor' or 'sequence_number_beneficiary'

create_genesis_block

Returns the genesis block.

check_add_genesis_block

If there are no blocks in the blockchain, persist the genesis block to the blockchain.

5

Quality assurance

Now that the market has been implemented, we focused on extending the test suite of the market and finding and fixing bugs. As per the requirements we have sent our code for evaluation to the Software Improvement Group (SIG). At SIG the code will be reviewed and given a rating representing how maintainable it is according to their model. The code will be sent for review twice, in this chapter we will discuss the outcome of these reviews. The original feedback reports can be found in appendix G.

5.1. Unit testing

During the development of the market, we wrote unit tests to be sure that every feature of the market worked properly, and keeps working as intended during the development process. Unit tests test the functionality of small units of code, in our case a unit test tests a single function. That way the unit tests are independent of each other, and a functionality only has to be tested once. For the unit tests we used the built-in *unittest* library and the *nose* library [32], with nose being used to run the test and generate reports.

In some tests it is necessary to use certain objects that do not need to be tested themselves, or that require substanial amount of data and parameters to initialize (such as Dispersy). To simplify the tests and to be sure that only the function that we wanted to test is being tested, we mocked other objects that were needed in the test. To create mocks we used the *mock* library [27].

Ideally all tests are run locally before an update is pushed to the revision control server, but this is not always the case. To make sure test-breaking changes are caught as soon as possible we employed continuous integration. For continuous integration Travis CI was used, along with Jenkins (provided by the Blockchain Lab). Not all tests were able to run on these continuous integration platforms, the requirements for running the GUI tests using PyQT's testing framework could not be installed. Nose was configured to ignore GUI tests to get around this issue.

To measure the extent of code tested by our tests, we took code coverage into account. Code coverage reports show what percentage of the code has been tested. If all of the lines of code in a file have been executed during the tests, the code coverage will be 100% for that specific file. These reports were generated by nose, which generated raw .xml files, which were then parsed by Jenkins's cobertura plugin or pycobertura.

Our coverage report can be found in table 5.1.

5.2. Integration testing

In this stage of the development process, we developed some integration tests to check the functionality of the whole program at once.

To perform the integration tests we set up some scenarios. We created different scenarios for each role, which means that we have scenarios for borrowers, financial institutions and investors.

The borrower's scenario creates a profile and then it sends a loan request to all banks. When a loan request has been sent it waits until it gets mortgage offers, and when mortgage offers have been received it accepts a random mortgage. After accepting a mortgage it waits until it gets investment bids, and accepts random investment bids when they have been received.

The investor's scenario creates a profile and then waits for campaigns to be available on the open market. When it has found some campaigns, it sends investment offers to random campaigns.

Module	Statements	Missing	Excluded	Coverage

Total	*2305*	*140*	*0*	*94%*

Table 5.1: Coverage report

The financial institution's scenario waits for loan requests to come in. When loan requests has been received it accepts them randomly.

To run the scenarios data has to be inserted. We generate fake data to put into the scenarios using the *Faker* [13] Python package.

By running the scenarios at the same time we could verify the functionality, performance and reliability of the market. We were able to view the GUI to see if the right information was displayed, and we were able to check the database to see if the objects have been saved correctly.

5.3. Code quality

In this section we will describe the feedback we got from SIG on the quality of our code, and describe how we addressed it. The full feedback can be found in appendix G.

The market application was sent to SIG for the first review on the 22nd of December 2016. The overall score for the system at this point was 4 out of 5 stars. Overall the code scored 5 stars for its small volume, lack of duplication and balance of components. 4 stars for the simple units, and loosely coupled modules and 3 stars for component independence.

The main issues identified by SIG were related to unit size and unit interfacing. Unit size refers to the length (lines of code) of functions, with each function longer than the average length lowering the score. The rationale behind having multiple shorter functions as opposed to one long function is to limit the amount of tasks a function has. This makes the function easier to understand and test. Unit interfacing relates to the amount of functions with an above-average number of parameters. Having an above-average amount of parameters usually indicates a lack of abstraction.

The unit size issues were primarily in the GUI related code. SIG noted that most of the longer functions were generated files by PyQt5. This has however already been solved as the GUI is now generated during run-time. A few classes have been refactored to split the functions into smaller units.

As for unit interfacing, the only function identified with an excessive number of parameters is the Signed-ConfirmPayload (defined in 4.4.1) with 13 parameters. The problem with refactoring this payload to accept an object consolidating related parameters is that this would complicate the encoders and decoders of the payload. As such we have decided to leave this constructor as it is. To improve readability however, all instances where this constructor will be called have been changed to use named parameters.

6

Discussion

In this chapter we will discuss the fulfillment of the project requirements listed in section 2.4 and discuss the challenges we have faced during the project. Finally we suggest recommendations for the future work.

6.1. Fulfillment of requirements

In this section we look at the project requirements, and we will discuss which requirements have been fulfilled. The requirements that have been fulfilled are marked green, and the requirements that haven't been fulfilled are marked red.

6.1.1. Must Have

- Borrower can place loan requests.

- Borrower can upload documents needed to apply for a mortgage.

- Borrower can see offers they get from investors and financial institutions.

- Borrower can accept offers they get from investors and financial institutions.

- Investor can see which campaigns are available.

- Investor can place an offer on a campaign.

- Financial institution can create a quote for a mortgage.

- Financial institution can see their pending loan requests.

- Financial institution can review pending loan requests.

- Financial institution can accept pending loan requests.

- Python 2 to be able to interface with Tribler and Dispersy.

- PyQt for the GUI.
  We used PyQt to control the GUI.

- Tests and coverage.
  We achieved this by creating unit tests and generating a coverage report every time we ran the tests.

- Full transparency. Everything open-source.
  All of our code is publicly accessible at `https://github.com/Jumba/mockchain-market`.

6.1.2. Should Have

- Borrower can reject offers they get from investors and financial institutions.

- Investor can see which campaign they have currently invested in.

- Financial institution can see which mortgages they currently have provided.

- Financial institution can reject pending loan requests.

- Scalable.
  Because we implemented the market upon Dispersy it is scalable. Tribler is proof for the scalability of Dispersy.

- Blockchain technology.
  We implemented a blockchain into the market to save agreements that have been made between teo parties.

6.1.3. Could Have

- Borrower can see which campaigns are available.

- Investor can resell their investment.

- Investor can invest passively.

- Financial institution can see which campaigns are available.

- Financial institution can determine the maximum interest rate that a borrower is allowed to pay an investor for the loan.

- Financial institution can recommend an interest rate that the borrower can pay to an investor for the loan.

- Secure storage and transfer of information.

- Encrypt and decrypt user documents.

6.1.4. Won't Have

- Borrower can see how much has already been paid off.

- Investor can see how much has already been paid off.

- Financial institution can see how much has already been paid off.

- Regulator can see the total financial health of all the active loans.

- Transactions can be done through the system.

- Smart contracts to ensure binding agreements between stakeholders.

- The system can do a risk assessment.

6.2. Challenges

During the development of the market we faced some challenges. In this section we will discuss those challenges, and how we worked through them.

One of the challenges was integrating Dispersy into the market. Getting dispersy to work was challenging due to its documentation. While it was helpful, we had trouble getting it to work because the example code was incorrect. With the help of the people at the Blockchain Lab this was resolved.

We also had some trouble understanding how Dispersy worked at first. Due to the lack of in-depth documentation, a lot of Dispersy workings had to be deduced from Dispersy unit tests and the implementation of functions.

We had some trouble with Qt5 during the first couple of weeks. While it has proven to be a great framework, some of the functionalities were not working without some unintuitive tweaking. Another problem that was encountered with Qt, and specifically PyQt5, was that the Python documentation was missing. Instead, the official website referred to the C++ implementation which in some cases had functions that were unknown in the Python version. We solved this with the help of the people at the Blockchain Lab.

Getting Dispersy to work alongside Qt proved to be an issue since both Qt5 and Dispersy have an event loop that were competing for attention. The solution was to start twisted [49], which is an event-driven networking engine that Dispersy uses, using a qt5reactor [37] which handles the Qt5 event loop.

Sending files proved to be an issue since we did not account for the maximum message size of 1500 bytes employed by Dispersy since it's based on UDP, and they're using the maximum MTU on the internet of 1500 bytes to prevent fragmentation. The solution we found was to send the files using the TFTP protocol.

6.3. Known issues and future work

Currently there are a few known issues present in the market application.

As mentioned in the previous section about the challenges encountered, the maximum message size in Dispersy is 1500 bytes. Currently it is possible for some messages to exceed this size, at which point they get dropped. While this is a rare occurrence, it needs to be resolved to ensure consistent and reliable messaging.

There are also some significant security risks with the current implementation of the models, which are described in section 3.3, and the way they are propagated through the network. Any malicious user can modify their market application to send models throughout the network with incorrect information. The integrity of models is not ensured by the program, and as such there is no way of knowing if a model that is being distributed through the network has been changed by a peer.

The market is also susceptible to attacks, due to its current implementation placing a significant amount of trust in the goodwill of the users. Take for instance a borrower looking for investors for his mortgage. Anyone can be an investor, pledge a certain amount to a campaign, and then disappear forever. By doing this repeatedly for all campaigns an attacker can easily disrupt the system by not giving genuine investors the chance to invest in a campaign. A solution to this is to move away from trusting the users, and implement a blockchain with smart contracts. Smart contracts can be used to enforce a contract by making sure that nobody can back away from an agreement. However, because smart contracts are currently a work in progress and have proven to be a complex matter, the functionality has been deemed as out of scope.

There can also be an issue when transferring documents. In the event that documents fail to be sent during the creation of a loan request, the program will retry multiple times to resend these files and send out the loan request even if not all documents were sent. The issue here is that the program will retry to send the documents only five times, which means that in some cases the bank does not receive all of the documents that belong to a loan request.

6.4. Conclusion

The goal of this project was to create a decentralized market in which mortgages can be crowdfunded. Users should be able to get a mortgage crowdfunded, and they should be able to invest in other users' crowdfunding campaigns.

To design the market we first researched some related initiatives. Using that research we defined the customer journeys for users with different goals using flowcharts. Using those flowcharts we started designing the GUI, the database, and we created an API to be able to get the right information from the database to show in the GUI.

After creating the core functionalities, we defined the information flow in the system. Using the infor-

mation flow we started integrating Dispersy into the market, to be able to identify users and send messages between users. Due to Dispersy having a maximum message size, we couldn't send the documents that are needed to apply for a mortgage through Dispersy. To be able to transfer those documents we made use of the TFTP protocol. To ensure that agreements made between two users (e.g. a financial institution giving a borrower a mortgage) can not be altered we implemented a blockchain.
The market that we developed for this project is a working decentralized platform that can connect users with different goals. Users that are in need of funding to buy a house are able to get a mortgage quote from financial institutions, and they are able to receive investment bids from users that want to invest. Financial institutions can receive mortgage applications from users that want to buy a house, and partially fund those users' mortgages. Users that are looking for an investing opportunity are able to view open crowdfunding campaigns, and they are able to place investment bids on those campaigns.

Project description: Open market for real-estate crowdsourcing

Market platforms such as AirBnB, eBay, Uber, and Blandlord.com bring supply and demand together. Based on our ongoing "blockchain-regulated markets" we now explore usage in various domains. This issue addresses an open market for crowdsourcing in real-estate.[33]

Outcome of initial brainstorm sketches:

Figure A.1: Brainstorm sketches

Sprints:

- Week 1-2: Write-up of context and understanding of problem, understand related initiatives. Describe at least 10 initiatives. Learn Python.

- Week 3-4: Apply Python. Visualize the concept using PyQT designer with 4 operational screens. Feedback round from bank.

- Week 5-6:

- Week 7-8:

Roadmap:
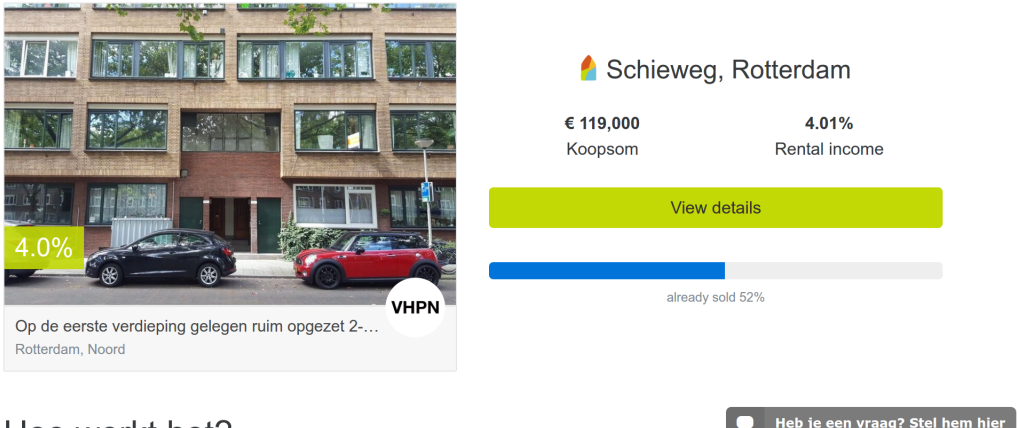

- Feb/Jan: we have 3 components ready in draft: operational market + GUI implemented in QT + business case

- till April: define API between market and business logic, create business logic core, integrate the market, business logic, and GUI.

- April: present MvP results

Various markets for real-estate already exist, such as:

Figure A.2: Blandlord is gestart in Rotterdam

Plus an operational crowdsourcing market, running locally which TUDelft indirectly has access to:

Figure A.3: Kapitaal op Maat

B

Infosheet

Crowdsourcing real-estate

Name of the client organization: ABN AMRO
Date of the final presentation: January 31, 2017

Description

For this project we were tasked with creating a scalable decentralized market for crowdfunding mortgages. Our client is ABN AMRO, who is collaborating with the TU Delft Blockchain Lab on the development of blockchain applications.

In the research phase we looked at related initiatives to understand more about crowdfunding real-estate and we had to find out how applying for a mortgage works, as our application involves people who want to apply for a mortgage. We also had to research dispersy and blockchain as we needed these technologies in our implementation of the product.

We used the scrum framework to keep the process in check and we tried to finish a new functionality every sprint. We held daily meetings within our group and weekly meetings with our coach. During the project we found that the initial scope was too big for this project, so we had to change the project description to fit the project duration.

The product that we developed for this project is a working decentralized platform that can connect users with different goals. Users that are in need of funding to buy a house are able to get a mortgage quote from financial institutions, and they are able to receive investment bids from users that want to invest. Financial institutions can receive mortgage applications from users that want to buy a house, and partially fund those users' mortgages. Users that are looking for an investing opportunity are able to view open crowdfunding campaigns, and they are able to place investment bids on those campaigns.

The outlook of the product was to create a program that could be reused in future projects. This is because the problem has been passed down from BEP group to BEP group with each iteration adding something to the main idea and implementation. It was important for us to make the program so that could be extended easily.

Members of the project team

Name	Katia Asmoredjo	Arthur Hovanesyan
Main contribution	API and GUI	GUI and document transfer

Name	Seu Man To	Calvin Wong Loi Sing
Main contribution	API and blockchain	API, database, and Dispersy

All team members took on the role of developer and contributed to writing the thesis and preparing the final presentation.

C

Mortgage Process

Welke documenten heb je nodig voor een hypotheek?
Als je een hypotheek afsluit, heb je nogal wat documenten nodig. Welke
documenten je nodig hebt voor een hypotheek, ligt aan de fase van het
hypotheekadviestraject. En aan jouw situatie. Sommige documenten heb
je al nodig bij het oriëntatiegesprek. Andere documenten heb je pas nodig
bij het afsluiten van je hypotheek.

Documenten voor hypotheek per fase
In onderstaande tabel zie je welke documenten je voor je hypotheek nodig
hebt in welke fase. Dit zijn de 4 fasen van het hypotheekadviestraject
waarin verschillende documenten nodig zijn:
1. Oriëntatie: berekening maximale hypotheek en voorbeeld
   maandlasten.
2. Hypotheekadvies: hypotheek samenstellen en producten vergelijken.
3. Hypotheekofferte aanvragen.
4. Hypotheek afsluiten: getekende hypotheekofferte naar de
   geldverstrekker.

Documenten voor hypotheek per situatie
In onderstaande tabel zie je welke documenten je voor je hypotheek nodig
hebt in welke situatie. De algemene documenten heb je altijd nodig. De
overige documenten alleen als die situatie voor jou geldt.
Alle documenten mogen een scan of kopie zijn, tenzij er "(origineel)"
achter staat.

Market API

Market API

class `market.api.api.MarketAPI`(*database*)   [source] 🔗

Create a MarketAPI object.

The constructor requires one variable, the *Database* used for storage.

> `accept_investment_offer`(*user*, *payload*)   [source]
>
> Accept an investment offer for the given user.
>
> The payload dictionary has the following composition
>
> | Key | Description |
> | --- | --- |
> | investment_id | The id of the investment |
>
> | | |
> | --- | --- |
> | **Parameters:** | • **user** (`User`) – The user accepting an investment offer.
 • **payload** (*dict*) – The payload containing the data for the `Investment`, as described above. |
> | **Returns:** | Returns True if successful, False otherwise. |
> | **Return type:** | bool |
> | **Raise:** | AssertionError if the user does not have a campaign assigned. |

> `accept_loan_request`(*bank*, *payload*)   [source]
>
> Have the loan request passed by the payload be accepted by the bank calling the function.
>
> The payload is as follows:
>
> | Key | Description |
> | --- | --- |
> | request_id | The `LoanRequest` id |
> | amount | The amount the bank is willing to finance |
> | interest_rate | The interest rate to be paid over the financed amount (float) |
> | default_rate | The default rate (float) |
> | max_invest_rate | The maximum investment interest rate (float) |

Key	Description
duration	The duration of the mortgage
risk	The risk associated with the loan

Parameters:
- **bank** (`User`) – The bank accepting the loan request.
- **payload** (*dict*) – The payload containing the data for the `Mortgage`, as described above.

Returns: Returns the loan request and the mortgage objects, or None if an error occurs.

Return type: tuple(LoanRequest, Mortgage) or None

`accept_mortgage_offer`(*user*, *payload*)   [source]

Accept a mortgage offer for the given user.

This action automatically rejects all other mortgage offers.

The payload dictionary has the following composition

Key	Description
mortgage_id	The id of the mortgage

Parameters:
- **user** (`User`) – The user accepting a mortgage offer
- **payload** (*dict*) – The payload containing the data for the `Mortgage`, as described above.

Returns: Returns True if successful, False otherwise.

Return type: bool

`create_campaign`(*user*, *mortgage*, *loan_request*)   [source]

Create a funding campaign with crowdfunding goal the difference between the price of the house and the amount requested from the bank. #TODO: Should it be more flexible?

Parameters:
- **user** (`User`) – The `User` for who the mortgage is being made
- **mortgage** – The `Mortgage` pertaining to the house being financed
- **loan_request** (`LoanRequest`) – The `LoanRequest` created prior to the mortgage being accepted.

Type:	mortgage: `Mortgage`
Returns:	True if created, False otherwise.
Return type:	bool or False

`create_loan_request`(*user*, *payload*) [source]

Create a Loan request for the given user using the payload provided.

The payload dictionary has the following composition

Key	Description
postal_code	The postal code of the house that is the target of the mortgage
house_number	The house number of the house that is the target of the mortgage
address	The address of the house that is the target of the mortgage
price	The total price of the house
seller_phone_number	The phone number of the seller
seller_email	The email of the seller
mortgage_type	The mortgage type: 1 = linear, 2 = fixed-rate
banks	List of banks the request should be sent to
description	Free text (unicode)
amount_wanted	The amount the borrower wants financed

Parameters:	• **user** (`User`) – The user creating a loan request • **payload** (*dict*) – The payload containing the data for the `House` and `LoanRequest`, as described above.
Returns:	The loan request object if successful, False otherwise
Return type:	`LoanRequest` or False

`create_profile`(*user*, *payload*) [source]

Creates a new profile and saves it to the database. The profile can either be a normal Profile or a BorrowersProfile, depending on the role given in the payload. Overwrites the old profile. The role 'FINANCIAL_INSTITUTION' can not have a profile, but the role will be set. Thus the function will return *True*.

The payload contains the following data. If the role is *1* for *BORROWER* then the last three fields must also be pushed.

Key	Description
role	The role id uit of the following tuple: ('NONE', 'BORROWER', 'INVEST
first_name	The user's first name
last_name	The user's last name
email	The user's email address
iban	The user's IBAN
phonenumber	The user's phone number
current_postalcode	The user's current postal code
current_housenumber	The user's current house number
current_address	The user's current address
documents_list	A list of documents

Parameters:
- **user** (`User`) – The user for whom a profile has to be made
- **payload** (*dict*) – The payload containing the data for the profile, as described above.

Returns: The Profile if a borrower or investor role was set, True if a bank role was set, False if the

payload is malformed :rtype: `Profile` or True or False

create_user() [source]

Create a dispersy user by generating a key public/private pair.

Returns None if the user creation process fails.

Returns: A tuple with the User object, the public key and the private key. The keys encoded in HEX.

Return type: (`User`, Public, Private) or None

db

Returns the database object

get_role(*user*) [source]

Get the role of the user from the database.

Parameters: user – The `User` whose role you want to retrieve

Returns: : Returns the role or None.

Return type: `User` or *None*

load_all_loan_requests(*user*)   [source]

Display all pending loan requests for the specific bank

Parameters:	user (`User`) – The bank `User`
Returns:	A list of lists containing the :any: 'LoanRequest's and the :any: 'House's
Return type:	list

load_bids(*payload*)   [source]

Returns a list of all bids on the selected campaign.

The payload dictionary has the following composition

Key	Description
mortgage_id	The id of the selected mortgage

Parameters:	**payload** (*dict*) – The payload containing the data for the `Investment`, as described above.
Returns:	A list :any: 'Investment' objects, a :any: 'House' object, and a :any: 'Campaign' object.
Return type:	list, House, Campaign

load_borrowers_loans(*user*)   [source]

Get the borrower's current accepted loans :param user: User-object, in this case the user has the role of a borrower :return: list of the loans, containing the current accepted loans, and the investor's profile

load_borrowers_offers(*user*)   [source]

Get all the borrower's offers(mortgage offers or loan offers) from the database. :param user: User-object, in this case the user has the role of a borrower :return: list of offers, containing either mortgage offers or investment offers :rtype: list

load_investments(*user*)   [source]

Get the pending and current investments list from the investor.

Parameters:	user (`User`) – The user whose investments need to be retrieved.
Returns:	A list containing lists with the investments, the house, the campaign, and the borrower's profile
Return type:	list

`load_mortgages`(*user*)   [source]

> Display all pending running mortgages for the bank
>
> > Parameters: **user** (`User`) – The bank `User`
> >
> > Returns: A list of lists containing the :any: 'Mortgage', the :any: 'House', the :any: 'Campaign',
>
> and the :any: 'BorrowersProfile' :rtype: list

`load_open_market`()   [source]

> Returns a list of all mortgages that have an active campaign going on.
>
> > Returns: A list containing lists with `Mortgage` objects, :any: 'House' objects, and :any: 'Campaign'
>
> objects. :rtype: list

`load_profile`(*user*)   [source]

> Load the given users profile.
>
> Depending on the user's role, it will return a `Profile` for an investor or a `BorrowersProfile` for a borrower. None for a financial institution
>
> > Parameters: **user** (`User`) – The user whose profile has to be loaded.
> >
> > Returns: `Profile` or `BorrowersProfile` or None

`load_single_loan_request`(*payload*)   [source]

> Display the selected pending loan request
>
> > Returns: A list of lists containing the :any: 'LoanRequest', the :any: 'Profile' of the borrower that wants a
>
> mortgage, and the :any: 'House' that the borrower wants :rtype: list

`login_user`(*private_key*)   [source]

> > Login a user by generating the public key from the private key supplied, and searching the user object in the database using the generated key.
>
> > Parameters: **private_key** (*str*) – The private key of the user encoded in HEX
> >
> > Returns: The logged in User if successful, None otherwise.

`place_loan_offer`(*investor*, *payload*)   [source]

Create a loan offer by an investor and save it to the database. This offer will always be created with status as 'PENDING' as the borrower involved is the only one allowed to change the status of the loan offer.

The payload contains the following data:

Key	Description
amount	The amount being invested
duration	The duration of the loan in months
interest_rate	The interest due to be paid over the loan
mortgage_id	The id of the mortgage being financed

Parameters:
- **investor** (`User`) – The investor wishing to invest in a mortgage by placing a loan offer.
- **payload** (*dict*) – The payload containing the data for the `Investment`, as described above.

Returns: The loan offer if successful, False otherwise.

Return type: `Investment` or False

`reject_investment_offer`(*user*, *payload*)   [source]

Decline an investment offer for the given user.

The payload dictionary has the following composition

Key	Description
investment_id	The id of the investment

Parameters:
- **user** (`User`) – The user rejecting an investment offer.
- **payload** (*dict*) – The payload containing the data for the `Investment`, as described above.

Returns: Returns True if successful, False otherwise.

Return type: bool

`reject_loan_request`(*user*, *payload*)   [source]

Decline an investment offer for the given user.

The payload dictionary has the following composition

Key	Description
request_id	The id of the loan request

Parameters:	• **user** (`User`) – The bank rejecting a loan request.
	• **payload** (*dict*) – The payload containing the data for the `LoanRequest`, as described above.

Returns:	Returns the rejected :any: 'LoanRequest' if successful, None otherwise.

Return type:	LoanRequest or None

`reject_mortgage_offer`(*user, payload*)　　[source]

Decline a mortgage offer for the given user.

The payload dictionary has the following composition

Key	Description
mortgage_id	The id of the mortgage

Parameters:	• **user** (`User`) – The user rejecting a mortgage offer
	• **payload** (*dict*) – The payload containing the data for the `Mortgage`, as described above.

Returns:	Returns True if successful, False otherwise.

Return type:	bool

`resell_investment`()　　[source]

Resell an invesment

Not implemented yet.

Raise:	*NotImplementedError*

`user_key`()　　[source]

Returns the user key the API communicates as.

SIG feedback

We had to submit our code to SIG twice for a code quality review. Below you can find their feedback.

The code of the system Decentralized Mortgage Marketplace scores 4 stars (3.6 out of 5.5) on our maintainability model, which means that the code is maintainable above average (the score ranges between 1 to 5 stars).

Overall, your code scored 5 stars for its small volume, the lack of duplication and its balance of components, 4 stars for its simple units and the loosely coupled modules and 3 stars for component independence. The lowest scores where in unit size and unit interfacing.

Components

Looking at the structure of the project, it looks like you have 4 different components on top level: configuration, test, front end and back end. Diving further on the market folder you have a proper componentization. The 5 stars you received for the component balance is due to the fact that we considered these inner components inside market.

Unit Size

For Unit Size we look at the percentage of code that is above average in length. Breaking down such methods into smaller pieces makes each component easier to understand, test, and is therefore easier to maintain. In the submitted code there are generated files by pyQt5 that they belong to the longer methods in the system, such as, the Ui_MainWindow(object). This unit is not hand written code, it doesn't need to be maintained and it can be created by the source .ui file. It really affected your score and you can avoid committing all of them. Another improvement could be to separate big units with many responsibilities into other reusable units like ProfileController.save_form(self). Comment lines such as "# Get the data from the forms" and "# Check if the user can switch roles" are a good indication that the code following fits in an autonomous unit. Therefore, it is advisable to take a critical look at the longer methods within the system and divide them where possible and avoid committing generated code.

Unit Interfacing

Unit Interfacing is depended on the percentage of code consists of units with an above-average number of parameters. An above-average number of parameters usually indicates a lack of abstraction. In addition, a large number of parameters often leads to confusion in calling the method, and in most cases also to longer and more complex methods. An example of a unit that needs refactoring is the SignedConfirmPayload.Implementation.__init__ which has 13 parameters that could be extracted in a object related (or even named) to beneficiary.

Conclusion

Overall your code scores above average. Hopefully, you can manage to maintain this level for the rest of the development or even reach the 5 stars.

Finally, the presence of 150 (unit) tests that are uploaded is in any case very promising. Hopefully, the volume of the test-code will also grow at the time that new functionality will be added.
